

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

Also solved by E. H. CLARKE, C. E. HORNE, and A. PELLETIER.

2749 [1919, 72]. Proposed by C. N. SCHMALL, New York City.

In the parabola, $y^2 = 4ax$, two normals to the curve are drawn at the ends of a focal chord. Show that the area between these normals and the curve is $20a^2/(3 \sin^3 2\phi)$ where ϕ is the angle between one of the normals and the x -axis.

SOLUTION BY H. M. ROESER, Bureau of Standards, Washington, D. C.

The tangents to a parabola at the extremities of a focal chord intersect on the directrix at right angles. (Tanner and Allen, *Analytic Geometry*, page 227.) The tangents and normals will, therefore, form a rectangle of which the focal chord is a diagonal and whose area is equal to the product of the lengths of the tangents from their intersection on the directrix to the points of tangency. The area sought is the area of one of the triangular halves of the rectangle plus two-thirds of the area of the other triangle or five-sixths of the area of the rectangle.

Let m = slope of one of the normals. Then $y = mx - 2am - am^3$ is the equation of one normal and $y = -x/m + 2a/m + a/m$ is the equation of the other normal. $y = -x/m - am$ is the equation of one tangent, and $y = mx + a/m$ is the equation of the other tangent. The tangents intersect at the point $(x, y) = [-a, a(1 - m^2)/m]$ and touch the curve at $(x, y) = [am^2, -2am]$ and $(x, y) = [a/m^2, 2a/m]$, respectively.

The lengths of the tangents are $l_1 = a(1 + m^2)\sqrt{1 + m^2/m}$ and $l_2 = a(1 + m^2)\sqrt{1 + m^2/m^2}$. The area sought is therefore $5l_1l_2/6 = 5a^2(1 + m^2)^3/6m^3 = 5a^2/(6 \sin^3 \phi \cos^3 \phi) = 20a^2/(3 \sin^3 2\phi)$.

2750 [1919, 72]. Proposed by A. CAMPBELL, St. Johnsbury, Vermont.

Given the base, the sum of the sides of the triangle and the difference of the base angles, to construct the triangle.

SOLUTION BY THE PROPOSER.

Let b , be the given base; $a + c$, the sum of the other two sides, and $\alpha = C - A$ the difference of the base angles.

On the line AK lay off $AC = b$ and at C construct an angle $ACD = \frac{1}{2}(C - A) = \frac{1}{2}\alpha$. Draw CE perpendicular to DC . With A as a center and a radius equal to $a + c$ describe an arc intersecting CE in F . Draw AF . Construct the angle BCF equal to the angle BFC . Then the triangle ABC is the required triangle.

For, triangle BCF is an isosceles triangle having its base angles equal by construction. Hence, $BC = BF$, and, therefore, $AB + BC = AF$.

Also, angle $CBF = \text{angle } A + \text{angle } C$, or angle MBC (BM being the bisector of angle CBF) = $\frac{1}{2}$ angle CBF = $\frac{1}{2}(\text{angle } A + \text{angle } C)$ = angle BCD = angle BDC = angle $A + \text{angle } DCA$; whence angle $DCA = \frac{1}{2}(\text{angle } C - \text{angle } A) = \frac{1}{2}\alpha$.
